The URL is on an internal LAN for a company whose name I cannot use. The site gets up to a few hundred hits per second supporting a telephone call center database. My company was asked to develop a web front end onto a TB data warehouse. The existing system (carefully crafted in C) was so slow people couldn't get their work done (e.g., 45-minute query times). We re-did the back end and slapped an interface on it using mod\_perl.

The first time the users saw it they asked for a "Stop" button like the existing system had so they could abort long-running queries. Then we went over where to put it with me running queries. They gave up on the idea because the data was returned too fast for them to hit a button.

Through 4+ weeks of User Acceptance Testing ("UAT") they asked for a few dozen changes in the reports. Few of them took longer than 20 minutes to implement. In several cases they got annoyed that the company email took longer to deliver the fix notice than make the change.

Using Perl we were also able to handle the database manglement software for tablespace and table creation, web site auth. and reporting code and most of the ETL process management code in one language. That also saved us quite a bit of work.
