MMWR
MORBIDITY AND MORTALITY WEEKLY REPORT

Escherichia coli O157:H7 Outbreak Linked to Commercially Distributed Dry-Cured Salami — Washington and California, 1994

From November 16 through December 21, 1994, a total of 20 laboratory-confirmed cases of diarrhea caused by *Escherichia coli* O157:H7 were reported to the Seattle-King County Department of Public Health (SKCDPH). In comparison, three cases were reported during October 1994. Epidemiologic investigation linked *E. coli* O157:H7 infection with consumption of a commercial dry-cured salami product distributed in several western states. Three additional cases subsequently were identified in northern California. This report summarizes preliminary findings from the outbreak investigation.

Washington

Infection with *E. coli* O157:H7 has been a reportable disease in Washington since 1987; cases are identified through routine follow-up of infections reported from local laboratories to the SKCDPH. Among the 20 case-patients, the median age was 6 years (range: 23 months to 77 years), 11 (55%) were male, and all resided in King County. Three patients required hospitalization, including a 2-year-old who developed hemolytic uremic syndrome (HUS).

Interviews with initial patients suggested that brand A dry-cured salami purchased at a local grocery chain was associated with illness. Based on these preliminary findings, during November 23–25, the grocery chain voluntarily withdrew brand A salami from its King County stores. To assess potential risk factors for infection, the SKCDPH conducted a case-control study of 16 cases and age-matched controls. A case was defined as culture-confirmed *E. coli* O157:H7 in a King County resident with onset of illness during November 15–29. Eleven (68%) case-patients and one (6%) control reported eating brand A dry-cured salami within 7 days before onset of illness (Mantel-Haenszel matched odds ratio=undefined; $p<0.01$). No other food item was significantly associated with infection.

All salami was purchased from the delicatessen counters of the local grocery chain. On November 28 and 29, environmental investigations were conducted at three of these delicatessens, and food samples were collected. No errors in food-handling practices were identified. *E. coli* O157:H7 was isolated from samples of brand A presliced dry-cured salami from two of the delicatessens on December 2 and

Escherichia coli — *Continued*

subsequently from a sample from a third delicatessen in the grocery chain. On December 2, the SKCDPH issued a press release informing the public of this problem and notified the U.S. Department of Agriculture (USDA). On December 6, the manufacturing company voluntarily recalled 10,000 pounds of implicated product labeled "Sell by May 7, 1995," which had been distributed in California, Oregon, and Washington. In addition, the company requested that their distributors suspend the sale of all of its products until the source of contamination was determined. The last case-patient had onset of illness on December 6.

Restriction fragment length polymorphism (Shiga-like toxin RFLP and lambda-RFLP) analysis by the University of Washington School of Public Health and Community Medicine determined that patterns were identical in 15 of 19 clinical isolates and in the three salami isolates. Sources for the matching isolates included 12 patients who ate salami, two secondary cases, and one person who ate sliced turkey purchased from a delicatessen where brand A dry-cured salami was sold, suggesting possible cross-contamination. The four nonmatching isolates were from specimens from patients who did not eat salami. These findings were confirmed at CDC by pulsed-field gel electrophoresis on a sample of outbreak-related isolates.

California

Three patients with laboratory-confirmed *E. coli* O157:H7 infection who reported consumption of brand A salami during the week before illness onset were hospitalized in northern California during November. Two patients resided in Sonoma County and one in Sacramento County. Patients were aged 4, 25, and 71 years; the 4-year-old developed HUS. Dates of onset ranged from November 17 through November 27. In addition, a 20-month-old resident of Sacramento who had consumed brand A dry-cured salami before onset of illness was hospitalized with postdiarrheal HUS on November 24. Although cultures of stool from this patient were negative for routine bacterial pathogens, screening for *E. coli* O157:H7 had not been performed before institution of antibiotic therapy. However, serum antibody to O157 antigen subsequently was detected at the Microbial Diseases Laboratory of the California State Department of Health Services (CSDHS).

CSDHS subsequently cultured *E. coli* O157:H7 from two samples of presliced brand A dry-cured salami obtained from stores in California.

Reported by: ER Alexander, MD, J Boase, MSN, M Davis, DVM, L Kirchner, C Osaki, MSPH, T Tanino, Seattle-King County Dept of Public Health, M Samadpour, PhD, Univ of Washington, P Tarr, MD, Children's Hospital and Medical Center, Seattle; M Goldoft, MD, S Lankford, J Kobyashi, MD, P Stehr-Green, DrPH, State Epidemiologist, Washington Dept of Health. Food Safety Inspection Svc, US Dept of Agriculture. Div of Training, Epidemiology Program Office; Foodborne and Diarrheal Diseases Br, Div of Bacterial and Mycotic Diseases, National Center for Infectious Diseases, CDC.

Editorial Note: *E. coli* O157:H7 was first recognized as a human pathogen in 1982 (*1*) and is now an important cause of bloody diarrhea and a leading cause of acute renal failure in children (*2*). Each year in the United States, *E. coli* O157:H7 infection accounts for a minimum 20,000 cases of illness and 250 deaths (CDC, unpublished data, 1995). In 1993, the Council of State and Territorial Epidemiologists recommended that *E. coli* O157:H7 be a nationally reportable disease and that clinical laboratories screen

Escherichia coli — *Continued*

at least all bloody stools for this pathogen (*3*). In response to increased culturing, during 1993–1994, a total of 46 clusters of *E. coli* O157:H7 infections involving an estimated 1300 persons were recognized in the United States. The outbreak described in this report highlights the critical role of both microbiologic surveillance for *E. coli* O157:H7 on diarrheal stool specimens submitted for bacterial culture and a reporting system to detect evolving communitywide outbreaks (*4,5*). As of January 1995, 32 states required that *E. coli* O157:H7 isolates be reported to the state health department, and an additional 16 states were considering establishing this requirement (CDC, unpublished data, 1995).

The identification of dry-cured salami as a source of *E. coli* O157:H7 infection in this outbreak extends the spectrum of food vehicles associated with this organism. Previous outbreaks have been associated with other foods of animal origin—including ground beef, roast beef, and raw milk (*2*)—and raw vegetables and apple cider possibly contaminated with cow feces (*6,7*). Dry-cured salami is not cooked but is usually produced through fermentation followed by drying. Specific manufacturing processes may vary among companies and for different types of salami. Experimental inoculation of a salami batter with *E. coli* O157:H7 has demonstrated that the organism survives but does not grow during fermentation, drying, and storage for 2 months at 39.2 F (4 C) (*8*).

On December 9, representatives of the USDA's Food Safety Inspection Service (FSIS) and 250 dry-sausage makers met to address the isolation of *E. coli* O157:H7 from this product. Industry representatives agreed to evaluate their production methods to assess the survival of *E. coli* O157:H7. FSIS will review industry findings and initiate any necessary changes in manufacturing processes (e.g., fermentation or time and temperature procedures).

The investigation in this report illustrates the usefulness of molecular subtyping techniques to distinguish outbreak strains of *E. coli* O157:H7 from others circulating in the community. Subtyping methods have included RFLP, pulsed-field gel electrophoresis, and phage typing (*9,10*). The combined use of methods may assist efforts to determine the relatedness of strains and assess epidemiologic associations (*10*). Prospective subtyping of *E. coli* O157:H7 strains may be used as an adjunct to microbiologic surveillance to detect clusters of related cases, guide interviewing, ascertain the source of infection, and prevent additional cases.

Emergency Department Surveillance for Weapon-Related Injuries — Massachusetts, November 1993–April 1994

During 1992, a total of 37,776 firearm-related deaths occurred in the United States (*1*), and in 1991, firearm-related deaths were the leading or second leading cause of injury death in 15 states (*2*). Because of limitations in data, however, the epidemiology of nonfatal firearm- and other weapon-related injuries has not been well characterized. To improve characterization of these problems, in 1989, the Massachusetts Department of Public Health (MDPH) began a pilot project to develop the first emergency-department–based statewide Weapon-Related Injury Surveillance System (WRISS) in the United States (*3*). All 85 hospital emergency departments in Massachusetts (1990 population: 6,016,425) now participate in this system. This report summarizes results from the first 6 months of statewide reporting (November 1993–April 1994), including previously unavailable statewide morbidity data on gunshot and stabbing injuries.

Since 1927, physicians in Massachusetts have been required to report to law enforcement authorities all gunshot wounds (GSWs) and all violence-related sharp instrument wounds (SIWs).* GSWs are defined as "all injuries resulting from, or caused by, the discharge of a gun, pistol, BB gun, or other air rifle or firearm." Violence-related SIWs are defined as nonself-inflicted "wounds or injuries caused by a knife or sharp or pointed instrument if, in the physician's judgment, a criminal act was involved." Although the statute requires reporting by all physicians, WRISS is a voluntary reporting system that has been implemented only in hospital-based emergency departments. The goal of WRISS is to ascertain all reportable weapon-related injuries treated in an emergency department regardless of outcome. WRISS does not ascertain nonfatal injuries treated outside the emergency department or injuries declared fatal at the scene whose victims are taken directly to the state medical examiner's office.

To facilitate reporting to WRISS and minimize reporting burden for providers, the existing police reporting form was modified and variables were added to a new voluntary reporting portion of the form. Completed forms are sent periodically from hospitals to the MDPH and state law enforcement authorities. Variables in WRISS include demographics (age, race/ethnicity, sex, and community of residence), location of incident, injury characteristics (type of weapon and location of wound), suspected drug or alcohol use, and injury severity (treated and released, admitted to hospital, or died). Reports for GSWs include type of injury (nonself-inflicted violence related; unintentional; or self-inflicted), and reports for violence-related GSWs and SIWs include victim-offender relationship and precipitating circumstance. Based on

*Mass. Gen. L. ch. 112, § 12A (1986).

Weapon-Related Injuries — Continued

periodic audits of records, reporting compliance is 70%–80% systemwide. Responses are unknown or missing for ≤25% of demographic variables, injury characteristics, and injury severity; 32%–68% of victim-offender relationships; and 26%–57% of precipitating circumstances.

During November 1993–April 1994, WRISS received reports of 1345 weapon-related injuries, including 451 GSWs and 894 SIWs. Based on these findings, estimated annual statewide rates were 15 GSWs per 100,000 residents and 30 violence-related SIWs per 100,000 residents. Of the 1345 injured persons, 1139 (85%) were male. The mean age was 27 years; 613 (46%) were aged 15–24 years, 396 (29%) were aged 25–34 years, and 267 (20%) were aged ≥35 years. Persons with GSWs were more likely to be hospitalized (240 [53%]) than persons with SIWs (258 [29%]).

Although 37% of persons in Massachusetts reside in large communities (population ≥50,000), 71% (300) of the GSW-related injuries occurred among persons who resided in large communities. Persons incurring GSWs in large communities were more likely than those in small communities to be aged <35 years (264 [88%] compared with 94 [76%]). In comparison, persons incurring SIWs in large communities were more likely than those in small communities to be aged ≥35 years (158 [25%] compared with 39 [17%]). In large communities, most (68%) GSW injuries were violence related, while in small communities 30% were violence related and 40% were unintentional (Table 1). Community size was not associated with victim-offender relationship or precipitating circumstances for either GSWs or SIWs. Among violence-related GSW incidents, when the victim-offender relationship was known, a higher proportion was associated with a stranger (28% in large communities and 22% in small communities) than with someone known by the victim (14% and 11%, respectively) while among SIW injuries, the offender was more likely to be known by the victim (34% and 39%) than to be a stranger (24% and 30%). For GSWs for which information on circumstance was known, argument or abuse was involved in 18% of incidents in large communities and 11% in small communities. Approximately half (46% in large communities and 52% in small communities) of incidents associated with SIWs involved argument or abuse.

The annualized crude rate for GSW injuries was 27 per 100,000 persons in large communities, compared with seven per 100,000 persons in small communities; however, the difference was greatest for violence-related GSWs (Table 2). Of the 451 GSWs, 60 (13%) were associated with BB guns and other nonpowder guns; of these, 45 (75%) occurred in small communities. In addition, BB guns and other nonpowder guns accounted for 19 (42%) of all reported weapon-related injuries to children aged <15 years. Most (36 [60%]) BB gun injuries were unintentional, and 13 (22%) were violence related; the remaining injuries were self-inflicted or of unknown intent.

Of the 894 SIWs, 636 (71%) occurred among persons in large communities (annualized crude rate: 57 per 100,000 residents), and 225 (25%) occurred in small communities (12 per 100,000 residents); information on community of residence was missing or unknown for 33 (4%). Most (734 [82%] of 894) injured persons were male, and the mean age was 28 years.

Reported by: V Ozonoff, C Barber, B Hume, L Jannelli, M Schuster, H McLaughlin, Massachusetts Dept of Public Health. Div of Violence Prevention, National Center for Injury Prevention and Control, CDC.

Editorial Note: National injury-control priorities include reductions in intentional, unintentional, and self-inflicted firearm injuries (*4*). Surveillance for weapon-related injuries—which involves the systematic collection of data about both fatal and nonfatal injuries—is an essential component in the development of a science-based approach to preventing these injuries and can assist in efforts to provide public education, develop legislation to reduce risks for weapon-related injuries, identify groups and communities at highest risk for such injuries, and evaluate prevention initiatives (*5*).

In Massachusetts, findings from WRISS routinely have been disseminated throughout the state to violence-prevention groups, hospitals, and policymakers through newsletters, presentations, and staff training. These data have been used by hospitals to obtain funding for victim services programs, design violence-prevention

educational materials, and train postgraduate medical staff. WRISS data also were used by an adolescent violence-prevention coalition to select neighborhoods for a teen mentoring program and by a community coalition in Boston in planning a gun buy-back initiative and related public education efforts. In addition, data have been requested by mayors and city councils and cited by the governor in a newspaper editorial addressing gun access.

Analysis of the statewide findings in Massachusetts indicates important variations in injury patterns that cannot be discerned based only on findings from localities. For example, the types of weapons and related injuries differed substantially between small and large communities. In addition, this emergency-department–based system enabled recognition of the magnitude of childhood injuries associated with BB guns. Although BB guns and other nonpowder guns are an important cause of injury among children (*6*), data about these injuries are not otherwise available because the injuries rarely cause death or result in hospital admission.

The MDPH is using WRISS data to establish an enhanced firearm surveillance system by linking it with mortality and hospital discharge data to estimate weapon-related injury costs, identifying potential risk factors through interviews with victims of unintentional GSWs, and interviewing violence-related GSW victims to assess data validity and provide additional information on victim-offender relationships and precipitating circumstances. In addition, WRISS data will be used for a new MDPH initiative to develop statewide surveillance for violence against women; data on victim-offender relationship and precipitating circumstance will be particularly important for that project.

The development of WRISS in Massachusetts has established the feasibility and utility of a statewide, emergency-department–based surveillance system for weapon-related injury. In addition, this system may provide guidance in developing surveillance systems in other states. In Massachusetts, implementation of a voluntary, emergency-department–based system for reporting to MDPH was facilitated by the

HIV Counseling and Testing — United States, 1993

Counseling and testing (CT) are important components of state and local human immunodeficiency virus (HIV)-prevention programs (*1*). Analysis of national data sources indicates that HIV-antibody tests are obtained from a variety of testing sites, including private physicians, hospitals, and outpatient clinics (66.7%), and publicly funded sites (33.1%) (*2*). This report uses data from CDC's 1993 Behavioral Risk Factor Surveillance System (BRFSS) to examine variations in rates of use of private and public HIV CT sites by state.

In 1993, a total of 49 states and the District of Columbia participated in the BRFSS, a state-specific population-based, random-digit–dialed telephone survey that collects information monthly from U.S. adults aged ≥18 years. Thirteen questions about HIV/AIDS-related knowledge and attitudes and HIV-antibody testing history during the preceding year were asked only to respondents aged ≤65 years. In 1993, a total of 84,039 persons responded to these questions (state-specific range: 993 to 3667). The state-specific median percentage of 82% of eligible respondents completed interviews (*3*). Data for each state were weighted by demographic characteristics and by selection probability; results are representative of persons aged 18–65 years in each state. Confidence intervals for percentages and estimated numbers of persons tested were based on standard errors that accounted for complex survey design (*4*).

A median of 25.5% of persons (range: 14.4% [Iowa] to 37.5% [Alaska]) answered yes to the question: "Except for donating or giving blood, have you ever had your blood tested for the AIDS virus infection?" (Table 1). The number (weighted estimate) of adults who had ever been tested for HIV was highest in California (6.3 million).

A median of 9.6% of persons (range: 4.1% [Maine and South Dakota] to 16.9% [District of Columbia]) reported obtaining HIV-antibody tests primarily for diagnostic

*For this study, diagnostic HIV tests were defined as those administered primarily to learn infection status rather than voluntary tests to qualify for insurance, military induction, immigration, marriage license application, or employment.

† Persons in this category were identified by one of three responses to the question "What was the main reason you had your last AIDS blood test?": "to find out if infected," "because of referral by doctor or health department or sex partner," or "for routine checkup." The response "for routine checkup" was included in "diagnostic" reasons to avoid excluding respondents who initiated a routine examination to determine whether they were infected with HIV.

§ Confidence interval.

HIV Counseling and Testing — Continued

reasons* (Table 1). Persons categorized as having obtained diagnostic HIV-antibody tests were identified by one of three responses to the question "What was the main reason you had your last AIDS blood test?": "to find out if infected," "because of referral by a doctor or health department or sex partner," or "for routine checkup†."

In 43 states and the District of Columbia, at least 50.0% (median: 60.9%) of respondents had obtained their last diagnostic test from a private physician, health maintenance organization, or private outpatient clinic (Table 2). A median of 16.2% of persons (range: 5.0% [North Dakota] to 37.6% [Mississippi]) had obtained their last diagnostic test at a publicly funded prevention site (including health departments; AIDS, sexually transmitted disease [STD], or tuberculosis clinics; and drug-treatment programs).

The estimated number of persons who obtained a diagnostic test at a publicly funded site during the preceding year correlated with the number of tests reported to CDC's HIV Counseling and Testing System by publicly funded sites in each state (*5*) (correlation coefficient=0.96; $p<0.01$).

A median of 60.7% of persons who had obtained their most recent diagnostic HIV-antibody test at a publicly funded site (range: 30.8% [New Jersey] to 95.7% [Oklahoma]) received counseling with their test results (Table 2). In comparison, a median of 28.2% of persons who had obtained their tests from a private site (range: 7.7% [Kentucky] to 77.3% [Oklahoma]) also received counseling. In most (90%) of the reporting areas, the number of persons who received counseling with their HIV test results was ≥1.5 times greater for persons tested at publicly funded sites than those tested at private sites.

Reported by the following BRFSS coordinators: S Jackson, MPA, Alabama; P Owen, Alaska; B Bender, Arizona; J Senner, PhD, Arkansas; B Davis, PhD, California; M Leff, MSPH, Colorado; M Adams, MS, Connecticut; F Breukelman, Delaware; C Mitchell, District of Columbia; D McTague, MS, Florida; E Pledger, MPA, Georgia; F Newfield, MPH, Hawaii; C Johnson, MPH, Idaho; B Steiner, MS, Illinois; R Guest, MPH, Indiana; P Busick, Iowa; M Perry, Kansas; K Bramblett, Kentucky; D Hargrove-Roberson, MSW, Louisiana; D Maines, Maine; A Weinstein, MA, Maryland; R Lederman, MPH, Massachusetts; H McGee, MPH, Michigan; N Salem, PhD, Minnesota; E Jones, MS, Mississippi; J Jackson-Thompson, PhD, Missouri; P Smith, Montana; S Huffman, Nebraska; E DeJan, Nevada; K Zaso, MPH, New Hampshire; G Boeselager, MS, New Jersey; P Jaramillo, MPA, New Mexico; C Maylahn, MPH, New York; G Lengerich, MD, North Carolina; D Young, MS, North Dakota; E Capwell, PhD, Ohio; N Hann, MPH, Oklahoma; J Grant-Worley, MS, Oregon; J Romano, MPH, Pennsylvania; J Hesser, PhD, Rhode Island; M Lane, MPH, South Carolina; B Miller, South Dakota; D Ridings, Tennessee; R Diamond, MPH, Texas; R Giles, Utah; R McIntyre, PhD, Vermont; S Carswell, MA, Virginia; K Holm, MPH, Washington; F King, West Virginia; E Cautley, MS, Wisconsin. Editorial Note: The findings from the 1993 BRFSS document a high degree of state-specific variability in self-reported HIV-antibody tests in the United States. This variability may reflect state-specific differences in such factors as the prevalence of HIV infection and HIV testing in high-risk groups, the presence and impact of HIV-prevention programs, and age distribution. The BRFSS estimates of the number of persons last tested for voluntary or diagnostic reasons at a publicly funded clinic

*For this study, diagnostic HIV-antibody tests were defined as those administered primarily to learn infection status rather than voluntary tests to qualify for insurance, military induction, immigration, marriage license application, or employment.

†This response was included in "diagnostic" reasons to avoid excluding respondents who initiated a routine examination to determine whether they were infected with HIV.

HIV Counseling and Testing — Continued

correlated highly with estimates from CDC's HIV Counseling and Testing System, and the median percentage of respondents ever tested for HIV (25%) is consistent with estimates based on CDC's National Health Interview Survey (22%).

Health-care visits to seek and obtain HIV tests are important opportunities to counsel persons about the risk for HIV infection and methods to reduce such risk (*1*). The data in this report indicate that, in most states, approximately threefold more persons reported having obtained their HIV test from a private provider than from a public site; however, persons who had obtained their test from a private provider were substantially less likely to have reported receiving counseling than those who obtained tests at a public site. This finding underscores the need for physicians and other health-care providers in private settings to offer HIV counseling at the time patients receive their HIV test results.

The findings in this report are subject to at least two limitations. First, the sample size of persons who reported having had an HIV-antibody test in individual states did not enable stratification by other respondent characteristics. For example, state-specific sample sizes precluded analysis to determine whether specific high-risk populations that obtained HIV-antibody testing also received counseling. Second, because the BRFSS is a telephone-based system, some persons at high risk for HIV infection most likely were excluded from the survey.

The BRFSS is a unique source for information about HIV-antibody testing behaviors of U.S. adults—particularly patterns of HIV testing outside of public clinics—and can be used both at the federal and state levels to improve HIV-prevention and intervention programs. Questions about CT in the 1993 BRFSS were developed based on input from state health departments; subsequent BRFSS surveys may incorporate additional HIV-related behavioral questions.

Clarification: Vol. 43, Nos. 51 & 52

The notice to readers "Recommended Childhood Immunization Schedule—United States, January 1995" (pages 959–960) stated that infants born to hepatitis B surface antigen (HBsAg)-positive mothers should receive immunoprophylaxis with 0.5 mL of hepatitis B immune globulin (HBIG) and 0.5 mL of hepatitis B vaccine administered at separate sites. Hepatitis B vaccines licensed in the United States are produced by Merck and Co., Inc. (Rahway, New Jersey), and SmithKline Beecham (Philadelphia) and are available in various concentrations. The recommended dose of hepatitis B vaccine for infants varies by manufacturer and HBsAg status of the mother (Table 1).

Merck and Co., Inc., recommends 2.5 μg of Recombivax HB® for infants of HBsAg-negative mothers and 5.0 μg for infants of HBsAg-positive mothers; SmithKline Beecham recommends 10 μg of Engerix-B® regardless of the mother's HBsAg status. Providers should know the HBsAg status of an infant's mother and consult the product package insert for the recommended vaccine dose.

Providers also should be aware that the Food and Drug Administration recently lowered the age-appropriate dose of Engerix-B® from 20 μg to 10 μg for adolescents 11–19 years of age (Table 1) (*1*).

TABLE 1. Recommended doses of currently licensed hepatitis B vaccines, by age or risk group

Group	Recombivax HB®*	Engerix-B®†
Infants of HBsAg-negative mothers	2.5 μg	10.0 μg
Infants of HBsAg-positive mothers	5.0 μg	10.0 μg
Children (Aged 1–10 years)	2.5 μg	10.0 μg
Adolescents (Aged 11–19 years)	5.0 μg	10.0 μg
Adults (Aged ≥20 years)	10.0 μg	20.0 μg
Dialysis patients and other immunocompromised persons	40.0 μg	40.0 μg

*Produced by Merck and Co. Inc. (Rahway, New Jersey).
†Produced by SmithKline Beecham (Philadelphia).

Addendum: Vol. 44, No. 8

In the article, "Exposure of Passengers and Flight Crew to *Mycobacterium tuberculosis* on Commercial Aircraft, 1992–1995," the following names should be added to the credits ("reported by") on the sixth line on page 139: A Ignacio, MD, D Morishige, RL Vogt, MD, State Epidemiologist, Communicable Disease Div, Hawaii Dept of Health.

Errata: Vol. 44, No. 8

In the article, "Exposure of Passengers and Flight Crew to *Mycobacterium tuberculosis* on Commercial Aircraft, 1992–1995," on page 138 in the first sentence under investigation 3, the length of flight is incorrect. The sentence should read, "In March 1993, a foreign-born passenger with pulmonary TB traveled on a *4½*-hour flight from Mexico to San Francisco."

In the article, "Use of Safety Belts—Madrid, Spain, 1994," the first sentence on page 151 should read, "Of 1063 phone numbers called to identify eligible households, 294 (27.7%) could not be contacted (no one answered or the line was busy), and 185 were excluded (because the phone number was commercial, no one aged ≥18 years was in the home at the time of the call, or respondents never traveled by vehicle)."

The *Morbidity and Mortality Weekly Report* (*MMWR*) Series is prepared by the Centers for Disease Control and Prevention (CDC). The data in the weekly *MMWR* are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business each Friday; compiled data on a national basis are officially released to the public the following Friday. Inquiries about the *MMWR* Series and material to be considered for publication should be addressed to Editor, *MMWR* Series, Mailstop C-08, CDC, 1600 Clifton Road, N.E., Atlanta, GA 30333; telephone (404) 332-4555.

The *MMWR* is available on a paid subscription basis for paper copy and free of charge in electronic format. For information about paid subscriptions, contact the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone (202) 783-3238. For electronic copy, send an e-mail message to *lists@list.cdc.gov* — the body content should read *subscribe mmwr-toc.* Electronic copy also is available from CDC's World-Wide Web server at *http://www.cdc.gov/* or CDC's file transfer protocol server at *ftp.cdc.gov.*
